

Linear Algebra 2 Notes

paraphrased by Tyler Wright

*An important note, these notes are absolutely **NOT** guaranteed to be correct, representative of the course, or rigorous. Any result of this is not the author's fault.*

1 Groups, Rings, and Fields

1.1 Definition of a Group

A group is a set G combined with a group operation $\circ : G \times G \rightarrow G$ such that:

- For all g, h, j in G , $g(hj) = (gh)j$ (associativity)
- There exists e in G such that $eg = ge = g$ for all g in G
- For all g in G , there exists g^{-1} in G such that $gg^{-1} = g^{-1}g = e$ where e is the identity of G .

1.2 Definition of a Homomorphism

A homomorphism between two groups G, H is a function $f : G \rightarrow H$ such that $f(gh) = f(g)f(h)$ for all g, h in G .

1.3 Properties of Homomorphisms

We can derive some properties of homomorphisms, for G, H groups, and $f : G \rightarrow H$ a homomorphism:

- The image of the identity in G is the identity in H
- The kernel of f is a subgroup of G
- The image of f is a subgroup of H
- Bijective homomorphisms are isomorphisms.

1.4 Definition of a Ring

A ring with unity is a set R along with an addition map $+$, and a multiplication map \circ where $+, \circ : R \times R \rightarrow R$ such that:

- $(R, +)$ is an abelian group (of which the identity is called zero)
- The multiplication operation is associative
- The multiplication operation has a two-sided identity not equal to the zero identity (called one)
- For all a, b, c in R , $a(b + c) = ab + ac$ and $(a + b)c = ac + bc$.

A ring is commutative if the multiplication operation is commutative.

1.5 Definition of a Subring

For the ring $R = (R', +, \circ)$ and S a set, S is a subring of R if $S \subseteq R'$ and $(S, +, \circ)$ is a ring.

1.6 Definition of a Ring Homomorphism

For rings with unity R and S , $f : R \rightarrow S$ is a ring homomorphism if for all a, b in R :

$$\begin{aligned}f(a + b) &= f(a) + f(b) \\f(ab) &= f(a)f(b) \\f(1_R) &= 1_S\end{aligned}$$

Essentially, this says that f is a homomorphism for the groups formed by R and S under addition and multiplication.

1.7 Definition of a Field

A field \mathbb{F} is a ring with unity with the following properties:

- $(\mathbb{F} \setminus \{0\}, \circ)$ is an abelian group.

1.8 Definition of the Field Characteristic

For a field \mathbb{F} , the field characteristic $\text{char}(\mathbb{F})$ is the smallest positive integer n such that:

$$\sum_{i=1}^n 1 = 1 + 1 + \dots + 1 = 0,$$

or zero if no such value n exists.

1.9 Definition of the Algebraic Closure of Fields

A field \mathbb{F} is called algebraically closed if all non-constant polynomials with coefficients in \mathbb{F} also has a root in \mathbb{F} .

2 Vector Spaces

2.1 Definition of a Vector Space

A vector space over a field \mathbb{F} is a set V with an addition operation $+: V \times V \rightarrow V$ and a scalar multiplication operations $\circ: \mathbb{F} \times V \rightarrow V$ such that for all a, b in \mathbb{F} and v, w in V :

- $(V, +)$ is an abelian group
- $1 \circ v = v$ where 1 is the multiplicative identity of \mathbb{F}
- $(ab) \circ v = a \circ (b \circ v)$
- $(a + b) \circ v = a \circ v + b \circ v$
- $a \circ (v + w) = a \circ v + a \circ w$.

2.2 Definition of a Subspace

For V a vector space over the field \mathbb{F} and W a set, W is a subspace of V if it is a subset of V and is a vector space with respect to the addition and scalar multiplication defined by V .

It is sufficient to verify that for any a in \mathbb{F} and v, w in W we have that $a(v + w)$ is in W .

2.3 Definition of a Linear Combination

For a set V with addition operation $+$, a field \mathbb{F} and n in \mathbb{N} , a linear combination of v_1, \dots, v_n in V is:

$$\sum_{i=1}^n a_i v_i,$$

for a_1, \dots, a_n in \mathbb{F} .

2.4 Definition of the Span

For a set V with addition operation $+$ and a field \mathbb{F} , the span of $W \subseteq V$ is the set of all the linear combinations of the values in W . Denoted by $\text{span}(W)$.

2.5 Definition of Linear Independence

For a vector space V and $W \subseteq V$, we say W is linearly dependent if there exists a non-trivial linear combination of all the vectors in W equal to zero (and linearly independent otherwise).

2.6 Properties of Linear Independence

For a vector space V with $W \subseteq V$:

- $0 \in W \Rightarrow W$ is linearly dependent
- W linearly independent \Rightarrow any $X \subseteq W$ is linearly independent
- If there's a linearly dependent subset of W , then W is linearly dependent.

2.7 Definition of a Basis

For a vector space V with $W \subseteq V$, if W is linearly independent and $\text{span}(W) = V$, we say that W is a basis of V .

Saying W is a basis is equivalent to saying that each vector in V can be **uniquely** written as a linear combination of vectors in W .

Additionally, for finite vector spaces, we have that all bases have the same amount of elements.

2.8 Definition of Dimension

For non-infinite bases, we say that the value of the basis is the dimension of the vector space it is a member of. Vector spaces with such bases are called finite-dimensional and all other vector spaces are infinite-dimensional.

By convention, for a vector space V , $\dim(\{0_V\}) = 0$.

2.9 Isomorphisms from Dimension

For V, W finite-dimensional vector spaces over \mathbb{F} with $\dim(V) = \dim(W)$, then $V \cong W$.

If we set $n = \dim(V)$, we have that $V \cong \mathbb{F}^n$.

Such an isomorphism can be found by mapping a vector in terms of some chosen basis vectors ($v = a_1v_1 + a_2v_2 + \cdots + a_nv_n$) to the coefficients (a_1, a_2, \dots, a_n) .

3 Linear Maps

3.1 Definition of a Linear Map

Let V, W be vector spaces over a field \mathbb{F} , we have that $f : V \rightarrow W$ is a linear map if for all a, b in \mathbb{F} and u, v in V :

$$f(au + bv) = af(u) + bf(v).$$

A bijective linear map is called an isomorphism. If $f : V \rightarrow W$ is an isomorphism, we say that V and W are isomorphic, denoted by $V \cong W$.

3.2 The Kernel of Linear Maps

Let V, W be vector spaces over a field \mathbb{F} , and $f : V \rightarrow W$ be a linear map. We define the kernel of f as:

$$\text{Ker}(f) = \{v \in V : f(v) = 0_{\mathbb{F}}\}.$$

Saying $\text{Ker}(f)$ is $\{0_{\mathbb{F}}\}$ is equivalent to saying f is injective.

3.3 The Image of Linear Maps

Let V, W be vector spaces over a field \mathbb{F} , and $f : V \rightarrow W$ be a linear map. We define the image of f as:

$$\text{Im}(f) = \{w \in W : \exists v \in V \text{ with } f(v) = w\}.$$

Saying $\text{Im}(f)$ is W is equivalent to saying f is surjective.

3.4 The Inverse of Linear Maps

For a bijective linear map f , the inverse of f is also linear.

3.5 Properties of the Set of Linear Maps

For V, W vector spaces over a field \mathbb{F} , we define $\mathcal{L}(V, W)$ to be the set of all linear maps from V to W .

3.6 The Rank-Nullity Theorem

For V, W finite-dimensional vector spaces and $f : V \rightarrow W$ a linear map, we have that:

$$\dim(V) = \dim(\text{Ker}(f)) + \dim(\text{Im}(f)).$$

Thus, for a linear map $f : V \rightarrow V$, if f is injective or surjective then it's an isomorphism.

4 Matrices

4.1 Definition of a Matrix

For m, n in $\mathbb{Z}_{>0}$ and \mathbb{F} a field. An $m \times n$ matrix with entries in \mathbb{F} is a map $M : [m] \times [n] \rightarrow \mathbb{F}$, more commonly written as $M = (a_{ij})$ representing the rectangular array of values held by M .

The set of all $m \times n$ matrices over \mathbb{F} is denoted by $M_{m \times n}(\mathbb{F})$.

4.2 Types of Matrix

For m, n in $\mathbb{Z}_{>0}$ and \mathbb{F} a field, let M be in $M_{m \times n}(\mathbb{F})$. We have the following types of matrix:

- **Square:** where $m = n$
- **Upper Triangular:** if $a_{ij} = 0$ for $i > j$
- **Lower Triangular:** if $a_{ij} = 0$ for $i < j$
- **Diagonal:** if $a_{ij} = 0$ for $i \neq j$
- **Symmetric:** if $a_{ij} = a_{ji}$
- **Anti-symmetric:** if $a_{ij} = -a_{ji}$.

4.3 Properties of the Space of Matrices

For m, n in $\mathbb{Z}_{>0}$ and \mathbb{F} a field, we have that $M_{m \times n}(\mathbb{F})$ is a vector space over \mathbb{F} where matrices are added and multiplied by scalars component-wise. So, for $M_1 = (a_{ij}), M_2 = (b_{ij})$ in $M_{m \times n}$ and c in \mathbb{F} we have:

$$\begin{aligned} cM_1 &= (ca_{ij}) \\ M_1 + M_2 &= (a_{ij} + b_{ij}). \end{aligned}$$

Additionally, the zero vector is $M_0 = (0)$ and the vector space has a basis consisting of M_{ij} where all entries are zero except the $(i, j)^{\text{th}}$ entry. This leads to the conclusion that the dimension is mn and thus that $M_{m \times n} \cong \mathbb{F}^{mn}$.

4.4 Matrix Multiplication

For a, b, c in $\mathbb{Z}_{>0}$ and a field \mathbb{F} , we can define the multiplication of the two matrices $X = (x_{ij})$ in $M_{a \times b}$ and $Y = (y_{ij})$ in $M_{b \times c}$ as follows:

$$XY = \left(\sum_{k=1}^b x_{ik} y_{kj} \right).$$

This operation is not commutative in general but is associative.

For A, B in M_n , we have that AB is also in M_n . This, along with matrix addition, makes M_n a ring with unity with multiplicative identity $I_n = (\delta_{ij})$. However, there exists A, B in M_n such that $AB = 0$ so, M_n is not a field.

4.5 Matrices of Linear Maps

For V, W vector spaces over a field \mathbb{F} , for some m, n in $\mathbb{Z}_{>0}$ we have $A = \{v_1, \dots, v_n\}$, $B = \{w_1, \dots, w_n\}$ bases for V and W respectively. Given f in $\mathcal{L}(V, W)$, the matrix associated to f (with respect to the bases A and B) is the $m \times n$ matrix:

$$M_{BA}(f) = (a_{ij}),$$

where we define a_{ij} by:

$$f(v_j) = \sum_{i=1}^m a_{ij} w_i,$$

for each j in $[n]$.

4.6 Matrices of Composed Linear Maps

For U, V, W vector spaces over a field \mathbb{F} , for some l, m, n in $\mathbb{Z}_{>0}$ we have $A = \{u_1, \dots, u_n\}$, $B = \{v_1, \dots, v_n\}$, $C = \{w_1, \dots, w_n\}$ bases for U, V, W respectively. Given g, f in $\mathcal{L}(V, W)$, we have:

$$M_{CA}(g \circ f) = M_{CB}(g)M_{BA}(f).$$

4.7 Transition Matrices

For a finite-dimensional vector space V , with an identity I and bases A, A' , we call $M_{A'A}(I) = C_{A'A}$ a transition matrix.

We have that $C_{A'A}$ is invertible and $C_{A'A}^{-1} = C_{AA'}$.

Essentially, the transition matrix transforms between bases.

4.8 Matrix Transitions

For a finite-dimensional vector space V , with $f : V \rightarrow V$ a linear operator, and bases A, B :

$$\begin{aligned} M_{BB}(f) &= C_{AB}^{-1} M_{AA}(f) C_{AB} \\ &= C_{BA} M_{AA}(f) C_{AB}. \end{aligned}$$

4.9 Similar Matrices

For matrices A', A , we say that A' and A are similar if there exists an invertible matrix C such that:

$$A' = C^{-1}AC.$$

This is denoted by $A' \sim A$. Similarity forms an equivalence relation on the space of square matrices.

If we have $A \sim A'$ and A represents some linear operator f for some basis B , then we have that for some basis B' , f has matrix A' .

5 Eigenvectors and Eigenvalues

5.1 Definition of an Eigenvectors and Eigenvalues

For a vector space V over \mathbb{F} with $f : V \rightarrow V$ a linear operator, a non-zero vector v in V is an eigenvector if $f(v) = \lambda v$ for some λ in \mathbb{F} which is called the eigenvalue corresponding to v .

5.2 Definition of an Eigenspace

For a vector space V over \mathbb{F} with $f : V \rightarrow V$ a linear operator and some eigenvalue λ , we define the eigenspace of λ as the set of eigenvectors with eigenvalue λ .

This is denoted by $E(\lambda)$ and $E(\lambda) \cup \{0_V\}$ forms a subspace of V . The dimension of $E(\lambda)$ is the geometric multiplicity of λ .
